

Tanning Module with a Housing

Description of the Invention

The invention relates to a tanning module having a housing, a tridimensional reflector disposed in the housing, and at least one discoid like radiation filter, the at least one
5 radiation filter covering the radiation-emitting area of the reflector and being disposed on a first side of the housing, at least one opening being provided in the reflector for the installation and electrical connection of a tanning radiator, and the reflector having its maximum cross section in the plane of the radiation-emitting area.

Such tanning modules are disclosed, for example, in DE 29 41 467 A1, wherein a
10 rectangular housing including fan and flow-directing baffles are used. The rectangular housing is divided into an air intake side and a delivery side, the tanning radiator being disposed on the delivery side and being indirectly cooled. The intake of cooling air, which flows along a heat filter in the housing wall, takes place on the air intake side of the housing through a lateral wall. On the delivery side of the housing the cooling air leaves the housing
15 through the same lateral wall as it previously entered the housing on the air intake side.

DE 195 16 603 A1 discloses a low-pressure viewing field for tanning apparatus, wherein a rectangular housing including reflector and filter pane is used. The housing is suitable for the installation of several UVC tubes. The entry of cooling air into the housing takes place through an opening between housing and filter pane, the cooling air flowing
20 along the tubes and leaving the housing again at the back of the housing.

DE 36 31 427 C2 describes a radiation apparatus with a rectangular housing, a reflector

The temperature of the reflector is thereby equalized. In the tanning module of the invention, additional flow guiding baffles can be dispensed with, since by means of the pyramidal shape the formation of fluidic "dead corners" is avoided. In the area of the opening in the reflector which serves for the installation and connection of a tanning radiator, air can also be drawn out of the reflector space and thus the tanning radiator can be directly cooled.

The tanning module according to the invention is appropriate for tanning radiators with an electrical power output in the range of 250W to 1000W. It is outstandingly useful in a great variety of tanning apparatus or medical apparatus for the irradiation of the face, the upper chest, the body area, and the leg or foot area. It is also possible to install it in ceilings, for the irradiation of floor areas from greater distances. The tanning module of the invention can basically be held in any kind of mounting so that it can radiate in all directions in a virtual sphere. Several tanning modules can be mounted side by side or one after another in order to produce a larger radiation field. Also, it is possible to operate with a separate fan for each tanning module or else to operate a plurality of tanning modules with one central fan.

It is preferred with the tanning module according to the invention that the radiation filter be aligned parallel to the radiation emitting area of the reflector. Thus the dimensions of the housing can be kept small. Advantageous in this connection is also the alignment of the base of the pyramid parallel to the at least one radiation filter.

The flattened apex of the pyramid can be formed on the one hand by a planar portion of

the housing wall, which can also be aligned parallel to the base of the pyramid. On the other hand the flattened apex of the pyramid can be formed by a vaulted portion of the housing wall, and it can be given a concave or convex shape in view of the base surface of the pyramid. The choice of the geometry of the flattened apex depends mainly on the conditions at the point of use of the tanning module.

The base of the pyramid can adjoin a rectangular housing wall area, which can serve, for example, to accommodate different radiation filters.

It has proven to be worth while to make the reflector in a cupular or tub-shape, the bottom of the cupular or tub-shaped reflector can be either vaulted or plane-parallel to the at least one radiation filter.

The perimeter of the reflector parallel to the radiation emitting area can then be a circle, an ellipse, a rectangle or a polygon. Especially preferred is a reflector formed of facets, in which case the perimeter of the reflector describes a polygon with twelve sides parallel to the radiation emitting area.

In particular the use of a reflector has proven useful whose height ranges from 90 mm to 95 mm and which is especially 93.6mm high. The dodecagon in the plane of the radiation emitting area has for this reflector a preferred maximum diameter (corner to corner) ranging from 210mm to 230mm, and amounts especially to 210mm. Moreover a reflector has proven useful whose height ranges from 110mm to 125mm and especially 118.7mm. In this case the dodecagon has a maximum diameter (corner to corner) ranging from 170mm to 200mm in the plane of the radiation emitting area and amounts especially to 184mm.

Moreover a reflector has proven useful having a height ranging from 75mm to 90mm and especially a height of 83.3mm. The dodecagon in this case has a maximum diameter (corner to corner) in the plane of the radiation emitting area ranging from 205mm to 235mm and amounts especially to 220mm.

5 The guidance of the cooling air in the housing is optimal when the housing has at least one air exhaust opening in the area of the pyramid. In that case a flange can be mounted on the air exhaust opening. Such a flange is suitable for the attachment of an air exhaust hose through which a central or off-center exhausting of air from the housing can be performed. To establish the necessary suction power at the air exhaust opening, a reducer plate may be present to reduce the size of the air exhaust opening. This is practical, for example, 10 whenever a plurality of tanning modules are used and they are at different distances from a central fan, i.e., one used simultaneously by all tanning modules or the air exhaust is performed in a kind of serial switching of the fan from one tanning module through at least one additional one.

15 The tanning module of the invention can be used very flexibly if one air exhaust opening is associated with each of three sides of the pyramid. Depending on the point of use and kind of use, one of the three air exhaust openings can be selected, for example, and the other two closed.

20 At least one mounting is preferably provided externally on the housing for electrical terminals or components, such components being, for example, an ignition device, a switch for filter plate protection and one grounding lug.

Between the housing and the reflector an intake plate is preferably situated, the radiation emitting area of the reflector being shifted upward or downward from the plane of the air intake plate, at least one intake opening being formed between the intake plate and the reflector, and the intake plate has an opening for the reflector, and in the vertical projection onto the at least one radiation filter, it has the size of the radiation emitting area.

With this arrangement of the reflector with respect to the intake plate, an annular intake opening is preferably formed between the intake plate and the reflector, through which cooling air can be drawn toward the outer wall of the reflector from the area between the radiation filter and the radiation emitting area of the reflector. However, a plurality of preferably annularly arranged intake openings may be formed between the intake plate and the reflector, in which case an alignment as symmetrical as possible has a beneficial effect on the uniformity of the cooling of the reflector and of the radiation filter. The temperature distribution on the radiation filter has a decisive influence on its transmission properties.

It has furthermore been found practical to use an air intake plate to fasten the reflector on all sides in the plane of the radiation emitting area to the housing, in which case the air intake plate has at least one intake opening and also a cut-out for the reflector, which has in its vertical projection onto the at least one radiation filter the size of the radiation emitting area.

If an intake plate with a rectangular perimeter is used and a reflector is also used whose perimeter parallel to the radiation emitting area describes a circle, an ellipse or a polygon, the at least one intake opening is preferably arranged in the area of at least one corner of the

intake plate.

The flow of cooling air is additionally optimized when four intake openings are formed in the intake plate and each intake opening is located in a corner of the intake plate.

It has proven especially useful if the at least one intake opening is enlarged along the sides of the intake plate. Preferred here is a trapezoidal intake opening, with the long side of the trapezoid pointing toward the reflector. Also, the long side of the trapezoid and its opposite side can be curved.

It is possible to fasten the reflector to the housing only through the intake plate. In that case various spacers can be provided between the intake plate and the reflector in order, for example, to form intake openings between the intake plate and the reflector.

The at least one radiation filter is to be preferably releasable from the housing with a swivelling mechanism. In that case the swivelling mechanism is to permit the radiation filter to tilt with respect to the base of the pyramid and it is to be possible to release the radiation filter from the housing only after the tilted radiation filter is displaced. In this manner a more user-friendly exchange of the radiation filter becomes possible and also any abrupt dropping of the radiation filter is avoided, since by means of such a swivelling mechanism the dropping of the radiation filter and thus its breakage can be effectively prevented.

It is advantageous if the at least one radiation filter is made rectangular, in which case its length and its width can range from 215mm to 240mm. Especially preferred is a radiation filter length of 230mm and a radiation filter width of 225mm. It has furthermore

proven worth while if the at least one radiation filter is an interference filter, since with it the ultraviolet content can be controlled and the visible portion of the light can be suppressed.

It is best if at least one air intake opening is present between the at least one radiation filter and the housing. Of course it must be assured that no unfiltered portion of the radiation leaves the housing through the air intake opening. It has likewise been found to be good if at least one air intake opening is present in the housing between the at least one radiation filter and the reflector. Thus cooling air can flow through the air intake opening into the area between the radiation filter and the radiation emitting area of the reflector and be drawn from there through exhaust openings to the outside of the reflector.

It has proven to be especially beneficial if a first radiation filter is present and plane-parallel thereto a second radiation filter, the second radiation filter being arrayed between the radiation emitting area of the reflector and the first radiation filter, and the first radiation filter is an interference filter. The second radiation filter is in that case preferably in the form of an ultraviolet filter or infrared filter.

For safety against breakage of the at least one radiation filter, at least one touch contact is preferably disposed on the housing, which rests on the at least one radiation filter. In that case the touch contact can be carried through the reflector, perpendicular to the radiation emitting area of the reflector, or else it can be carried through the intake plate perpendicular to the radiation emitting area of the reflector. The touch contact, however, can also be arranged on the intake plate and rest on the at least one radiation filter. In the event of the breakage of the monitored radiation filter, the change in the position of the touch contact

interrupts the power supply to the tanning radiator and the user is protected against an uncontrolled dose of radiation.

In the area of the opening of the reflector a base is provided for the mechanical and electrical hook-up of a tanning radiator.

5 Between the at least one radiation filter and the intake plate a cover plate can be associated which is arranged at a distance from the intake plate and which has a cut-out which in vertical projection onto the at least one radiation filter has the magnitude of the radiation emitting area of the reflector. This cover plate protects the eye of the user against any intake openings present in the intake plate for cooling air.

The Figures 1 to 4 are intended by way of example to explain the tanning module of the invention.

Figure 1 shows the tanning module including radiation filter and electric connections in a three-dimensional view,

Figure 1a shows the tanning module from Figure 1 in a side view,

Figure 1b shows the tanning module from Figure 1 from the front,

Figure 1c shows the tanning module from Figure 1 from below,

Figure 1d shows the tanning module from Figure 1b in section,

Figure 1e shows the tanning module from Figure 1a in section,

20 Figure 2 shows an air intake plate including four intake openings,

Figure 2a shows the tanning module from Figure 1 without radiation filter and

reflector,

Figure 3 shows a three-dimensional view of several tanning modules,

Figure 4 shows three tanning modules, arranged as in Figure 3, in section.

Figure 1 shows a tanning module according to the invention including radiation filter and electric connections in a three-dimensional view. The housing 1 has on one side the shape of a four-sided pyramid 1a with rectangular base and flattened pyramid apex 1b. On three sloping sides of the pyramid are circular air exhaust openings, two of them closed, and one provided with a flange 5. The rectangular base is adjoined by a rectangular housing wall portion 1c. Into this is hooked, through opening 13, the radiation filter 2 (see Figure 1b) which is within a frame structure, an air intake opening 10 remaining free. The frame structure for the radiation filter 2 contains among other things a frame 18 and the cover plate 17 (see Figure 1b). The locking button 14 holds the radiation filter 2 in its position by means of a snap fastening mechanism which, upon opening, shuts off the tanning radiator. If the locking button is opened, the radiation filter 2 folds down with the frame structure, while the opening 13 prevents any complete drop-out. Not until the radiation filter 2 has been pulled forward is it completely releasable from the housing 1. On the side of the pyramid that has no air exhaust opening, a touch contact 11, starter 15 and electrical connections 16 are installed.

Figure 1a shows the tanning module from Figure 1 in a side view.

Figure 1b shows the front of the tanning module from Figure 1, wherein the arrangement of the touch contact 11 on the radiation filter 2 can now be clearly seen.

Moreover, a mounting 7 can be seen on which the starter 15 is installed.

Figure 1c shows the tanning module from Figure 1 from below, the frame 18 and the cover plate 17 being visible. The transparent radiation filter 2 (see Figure 1b) is between the frame 18 and the cover plate 17. A twelve-angled reflector 3 is present, which is formed of the facets 3a. The touch contact 11 is brought through the cover plate 17 and rests on the radiation filter 2 (see Figure 1b). In the center of the reflector 3 the base 12 can be seen, including the electrical terminals for the tanning radiator.

Figure 1d shows the tanning module from Figure 1b in section; here a first radiation filter 2a and a second radiation filter 2b are present. The reflector 3 is connected through an intake plate 8 to the housing 1.

Figure 1e shows the tanning module from Figure 1a in section, where a first radiation filter 2a and a second radiation filter 2b are present. The air exhaust opening 4 on which the flange 5 is mounted can be seen. The reflector 3 is connected through the intake plate 8 to the housing 1.

Figure 2 shows an intake plate 8 including a cut-out 8a for the reflector 3, as well as four trapezoidal intake openings 9. Moreover, an opening 11a is present for the touch contact 11 (see Figure 1b).

Figure 2a shows the tanning module from Figure 1c without the radiation filter 2 and reflector 3, wherein the view of the pyramid 1a and pyramid apex 1b is clear from the inside.

Figure 3 shows a three-dimensional view of a plurality of tanning modules mounted one beside the other. On the left is a tanning module with radiation filter 2 and frame 18 in

place. In the center is shown a tanning module with the radiation filter including the tanning radiator folded down, and the intake plate with circular intake openings 9 and the reflector 3 can be seen. On the right is shown a tanning module without radiation filter and without tanning radiator. All three modules are provided with air exhaust hoses 6.

5 Figure 4 shows three tanning modules in section which are arranged as in Figure 3. A first radiation filter 2a and a second radiation filter 2b are present.
